STATEMENT ON IN-STATE ELECTRICITY GENERATION AND COAL

Arden State Energy Office, at the request of the Environmental Quality Board

1. Coal

There are no coal-fired electricity generating units in Arden. The last such unit was retired and dismantled. No generator in the State holds a coal supply contract, no seller has filed a return reporting coal sales in any year of the current series, and the Office holds no record of coal deliveries into the State for combustion.

The Office is asked periodically whether coal moves through Arden ports. It does not; the port authority's commodity schedule does not include coal.

2. Generation mix

Natural gas is the largest source of in-state generation, followed by wind. 46.3 per cent of generation was gas-fired in the most recent year, 37.0 per cent wind, 12.6 per cent solar, and the balance hydro, biomass and oil-fired peaking capacity. The State is a net importer of electricity in winter and a net exporter in spring.

3. Consequence for the assessment

Because there are no coal sales in Arden, the coal emission factor in the Board's annex has no application to any seller. The product mix of every seller filing a return consists of oil and refined products, natural gas, or a combination of the two.

4. Oil-fired peaking capacity

4 oil-fired peaking units remain in service with a combined nameplate capacity of 320 megawatts. Their fuel is purchased from sellers filing returns and is included in those sellers' reported in-state sales of refined products.

Prepared 6 August 2025.
